

Which type of vanadium is used in all-vanadium liquid flow batteries

Overview

The active substance of the electrolyte of the all-vanadium flow battery is vanadium sulfate, in which vanadium is the active element. The battery uses vanadium's ability to exist in a solution in four different oxidation. The battery uses vanadium ions, derived from vanadium pentoxide (V_2O_5), in four different oxidation states. These vanadium ions are dissolved in separate tanks and pumped through a central chamber where they exchange electrons, generating electricity. During the charging process, an ion exchange happens across a membrane. There are currently a limited number of papers published addressing the design considerations of the VRFB, the limitations of each. Energy storage systems are used to regulate this power supply, and Vanadium redox flow batteries (VRFBs) have been proposed as one such method to support grid integration.
